Preface	xiv
Acknowledgements	xv
Abstract	1
1. Introduction	1
2. Data and data distribution	1
2.1 Data sources	2
2.2 Data quality control	2
2.2a Duplicate elimination	2
2.2b Range checking	3
2.2c Statistical checks	3
2.2d Subjective elimination of data	3
2.2e Representativeness of the data	3
2.2f Calculations of derived quantities	4
3. Data processing procedures	4
3.1 Vertical interpolation to standard levels	4
3.2 Methods of analysis	4
3.2a Overview	4
3.2b Derivation of Barnes (1964) weight function	6
3.2c Derivation of Barnes (1964) response function	7
3.2d Derivation of Barnes (1973) weight function	7
3.2e Choice of response function	8
3.2f First guess field determination	8
3.3 Choice of objective analysis procedures	9
3.4 Choice of spatial grid	9
4. Results	10
4.1 Annual mean oxygen at standard levels	10
4.1a Explanation of standard level figures	10
4.1b Standard level analyses	10
4.2 Basin zonal averages	10
4.3 Basin mean profiles and volume means	10
5. Summary	11
6. Future work	11
7. References	13
8. Appendix A: Distribution of observations of dissolved oxygen at all standard levels in the world ocean for the annual composition period	24
9. Appendix B: Annual oxygen at standard levels in the world ocean	31

10. Appendix C: Global and basin zonal averages of annual mean oxygen	52
11. Appendix D: Global and basin volume averages of annual mean oxygen	56
12. Appendix E: Annual mean Apparent Oxygen Utilization at standard levels in the world ocean	62
13. Appendix F: Global and basin zonal averages of annual mean Apparent Oxygen Utilization	83
14. Appendix G: Global and basin volume averages of annual mean Apparent Oxygen Utilization	87
15. Appendix H: Annual mean oxygen saturation at standard levels in the world ocean	93
16. Appendix I: Global and basin zonal averages of annual mean oxygen saturation	114
17. Appendix J: Global and basin volume averages of annual mean oxygen saturation	118
18. Appendix K: Area and volume basin means	124
19. Appendix L: Seasonal distribution of observations of oxygen at standard levels in the world ocean	131
20. Appendix M: Seasonal mean oxygen at standard levels in the world ocean	139
21. Appendix N: Seasonal mean minus annual mean oxygen at standard levels in the world ocean	147
22. Appendix O: Seasonal mean Apparent Oxygen Utilization at standard levels in the world ocean	155
23. Appendix P: Seasonal mean minus annual mean Apparent Oxygen Utilization oxygen at standard levels in the world ocean	163
24. Appendix Q: Seasonal mean oxygen saturation at standard levels in the world ocean	171
25. Appendix R: Seasonal mean minus annual mean oxygen saturation at standard levels in the world ocean	179

List of Tables

- Table 1 Distribution with depth of the number of one-degree squares of ocean (Ocean ODSQS), the total number (N) of oxygen observations, and the number of one-degree squares (ODSQS) containing observations of oxygen.
- Table 2 Acceptable distances for "inside" and "outside" values used in the Reiniger-Ross scheme for interpolating observed level data to standard levels.
- Table 3 Response function of the objective analysis scheme as a function of wavelength.
- Table 4 Basin identifiers and depths of "mutual exclusion" used in this study.

List of Figures

- Figure 1 Number of oxygen profiles as a function of year for each season.
Figure 2 Number of oxygen observations at as a function of year A) at the sea surface B) at 1000 m C) at 2000 m.
Figure 3 Distribution of oxygen observations as a function of depth for the globe and the Northern and Southern Hemispheres.
Figure 4 Division of world ocean into individual basins.

APPENDIX A

- Figure A1 Annual distribution of oxygen observations at the surface.
Figure A2 Annual distribution of oxygen observations at 30 m depth.
Figure A3 Annual distribution of oxygen observations at 50 m depth.
Figure A4 Annual distribution of oxygen observations at 75 m depth.
Figure A5 Annual distribution of oxygen observations at 100 m depth.
Figure A6 Annual distribution of oxygen observations at 125 m depth.
Figure A7 Annual distribution of oxygen observations at 150 m depth.
Figure A8 Annual distribution of oxygen observations at 250 m depth.
Figure A9 Annual distribution of oxygen observations at 400 m depth.
Figure A10 Annual distribution of oxygen observations at 500 m depth.
Figure A11 Annual distribution of oxygen observations at 700 m depth.
Figure A12 Annual distribution of oxygen observations at 900 m depth.
Figure A13 Annual distribution of oxygen observations at 1000 m depth.
Figure A14 Annual distribution of oxygen observations at 1200 m depth.
Figure A15 Annual distribution of oxygen observations at 1300 m depth.
Figure A16 Annual distribution of oxygen observations at 1500 m depth.
Figure A17 Annual distribution of oxygen observations at 1750 m depth.
Figure A18 Annual distribution of oxygen observations at 2000 m depth.
Figure A19 Annual distribution of oxygen observations at 2500 m depth.
Figure A20 Annual distribution of oxygen observations at 3000 m depth.
Figure A21 Annual distribution of oxygen observations at 4000 m depth.

APPENDIX B

- Figure B1 Annual mean oxygen (ml/l) at the surface.
Figure B2 Annual mean oxygen (ml/l) at 30 m depth.
Figure B3 Annual mean oxygen (ml/l) at 50 m depth.
Figure B4 Annual mean oxygen (ml/l) at 75 m depth.
Figure B5 Annual mean oxygen (ml/l) at 100 m depth.
Figure B6 Annual mean oxygen (ml/l) at 125 m depth.
Figure B7 Annual mean oxygen (ml/l) at 150 m depth.
Figure B8 Annual mean oxygen (ml/l) at 250 m depth.
Figure B9 Annual mean oxygen (ml/l) at 400 m depth.
Figure B10 Annual mean oxygen (ml/l) at 500 m depth.
Figure B11 Annual mean oxygen (ml/l) at 700 m depth.
Figure B12 Annual mean oxygen (ml/l) at 900 m depth.
Figure B13 Annual mean oxygen (ml/l) at 1000 m depth.
Figure B14 Annual mean oxygen (ml/l) at 1200 m depth.
Figure B15 Annual mean oxygen (ml/l) at 1300 m depth.
Figure B16 Annual mean oxygen (ml/l) at 1500 m depth.
Figure B17 Annual mean oxygen (ml/l) at 1750 m depth.

- Figure B18 Annual mean oxygen (ml/l) at 2000 m depth.
 Figure B19 Annual mean oxygen (ml/l) at 2500 m depth.
 Figure B20 Annual mean oxygen (ml/l) at 3000 m depth.
 Figure B21 Annual mean oxygen (ml/l) at 4000 m depth.

APPENDIX C

- Figure C1 Annual global zonal average (by one-degree squares) of oxygen (ml/l).
 Figure C2 Annual Pacific zonal average (by one-degree squares) of oxygen (ml/l).
 Figure C3 Annual Atlantic zonal average (by one-degree squares) of oxygen (ml/l).
 Figure C4 Annual Indian zonal average (by one-degree squares) of oxygen (ml/l).

APPENDIX D

- Figure D1a Annual global oxygen (ml/l) basin means (0-1000 m).
 Figure D1b Annual global oxygen (ml/l) basin means (0-5500 m).
 Figure D2a Annual Pacific oxygen (ml/l) basin means (0-1000 m).
 Figure D2b Annual Pacific oxygen (ml/l) basin means (0-5500 m).
 Figure D3a Annual Atlantic oxygen (ml/l) basin means (0-1000 m).
 Figure D3b Annual Atlantic oxygen (ml/l) basin means (0-5500 m).
 Figure D4a Annual Indian oxygen (ml/l) basin means (0-1000 m).
 Figure D4b Annual Indian oxygen (ml/l) basin means (0-5500 m).
 Table D1a Annual oxygen (ml/l) basin means and standard errors for the world ocean and Pacific Ocean as a function of depth.
 Table D1b Annual oxygen (ml/l) basin means and standard errors for the Atlantic Ocean and Indian Ocean as a function of depth.

APPENDIX E

- Figure E1 Annual mean Apparent Oxygen Utilization (ml/l) at the surface.
 Figure E2 Annual mean Apparent Oxygen Utilization (ml/l) at 30 m depth.
 Figure E3 Annual mean Apparent Oxygen Utilization (ml/l) at 50 m depth.
 Figure E4 Annual mean Apparent Oxygen Utilization (ml/l) at 75 m depth.
 Figure E5 Annual mean Apparent Oxygen Utilization (ml/l) at 100 m depth.
 Figure E6 Annual mean Apparent Oxygen Utilization (ml/l) at 125 m depth.
 Figure E7 Annual mean Apparent Oxygen Utilization (ml/l) at 150 m depth.
 Figure E8 Annual mean Apparent Oxygen Utilization (ml/l) at 250 m depth.
 Figure E9 Annual mean Apparent Oxygen Utilization (ml/l) at 400 m depth.
 Figure E10 Annual mean Apparent Oxygen Utilization (ml/l) at 500 m depth.
 Figure E11 Annual mean Apparent Oxygen Utilization (ml/l) at 700 m depth.
 Figure E12 Annual mean Apparent Oxygen Utilization (ml/l) at 900 m depth.
 Figure E13 Annual mean Apparent Oxygen Utilization (ml/l) at 1000 m depth.
 Figure E14 Annual mean Apparent Oxygen Utilization (ml/l) at 1200 m depth.
 Figure E15 Annual mean Apparent Oxygen Utilization (ml/l) at 1200 m depth.
 Figure E16 Annual mean Apparent Oxygen Utilization (ml/l) at 1500 m depth.
 Figure E17 Annual mean Apparent Oxygen Utilization (ml/l) at 1750 m depth.
 Figure E18 Annual mean Apparent Oxygen Utilization (ml/l) at 2000 m depth.
 Figure E19 Annual mean Apparent Oxygen Utilization (ml/l) at 2500 m depth.
 Figure E20 Annual mean Apparent Oxygen Utilization (ml/l) at 3000 m depth.
 Figure E21 Annual mean Apparent Oxygen Utilization (ml/l) at 4000 m depth.

APPENDIX F

- Figure F1 Annual global zonal average (by one-degree squares) of Apparent Oxygen Utilization (ml/l).
Figure F2 Annual Pacific zonal average (by one-degree squares) of Apparent Oxygen Utilization (ml/l).
Figure F3 Annual Atlantic zonal average (by one-degree squares) of Apparent Oxygen Utilization (ml/l).
Figure F4 Annual Indian zonal average (by one-degree squares) of Apparent Oxygen Utilization (ml/l).

APPENDIX G

- Figure G1a Annual global Apparent Oxygen Utilization basin means (0-1000 m).
Figure G1b Annual global Apparent Oxygen Utilization (ml/l) basin means (0-5500 m).
Figure G2a Annual Pacific Apparent Oxygen Utilization (ml/l) basin means (0-1000 m).
Figure G2b Annual Pacific Apparent Oxygen Utilization (ml/l) basin means (0-5500 m).
Figure G3a Annual Atlantic Apparent Oxygen Utilization basin means (0-1000 m).
Figure G3b Annual Atlantic Apparent Oxygen Utilization basin means (0-5500 m).
Figure G4a Annual Indian Apparent Oxygen Utilization (ml/l) basin means (0-1000 m).
Figure G4b Indian Apparent Oxygen Utilization (ml/l) basin means (0-5500 m).
Table G1a Annual Apparent Oxygen Utilization (ml/l) basin means and standard errors for the world ocean and Pacific Ocean as a function of depth.
Table G1b Annual Apparent Oxygen Utilization (ml/l) basin means and standard errors for the Atlantic Ocean and Indian Ocean as a function of depth.

APPENDIX H

- Figure H1 Annual mean oxygen saturation (%) at the surface.
Figure H2 Annual mean oxygen saturation (%) at 30 m depth.
Figure H2 Annual mean oxygen saturation (%) at 50 m depth
Figure H4 Annual mean oxygen saturation (%) at 75 m depth.
Figure H5 Annual mean oxygen saturation (%) at 100 m depth.
Figure H6 Annual mean oxygen saturation (%) at 125 m depth.
Figure H7 Annual mean oxygen saturation (%) at 150 m depth.
Figure H8 Annual mean oxygen saturation (%) at 250 m depth.
Figure H9 Annual mean oxygen saturation (%) at 400 m depth.
Figure H10 Annual mean oxygen saturation (%) at 500 m depth
Figure H11 Annual mean oxygen saturation (%) at 700 m depth.
Figure H12 Annual mean oxygen saturation (%) at 900 m depth.
Figure H13 Annual mean oxygen saturation (%) at 1000 m depth.
Figure H14 Annual mean oxygen saturation (%) at 1200 m depth.
Figure H15 Annual mean oxygen saturation (%) at 1300 m depth.
Figure H16 Annual mean oxygen saturation (%) at 1500 m depth.
Figure H17 Annual mean oxygen saturation (%) at 1750 m depth.
Figure H18 Annual mean oxygen saturation (%) at 2000 m depth.
Figure H19 Annual mean oxygen saturation (%) at 2500 m depth.
Figure H20 Annual mean oxygen saturation (%) at 3000 m depth.
Figure H21 Annual mean oxygen saturation (%) at 4000 m depth.

APPENDIX I

- Figure I1 Annual global zonal average (by one-degree squares) of oxygen saturation (%).
Figure I2 Annual Pacific zonal average (by one-degree squares) of oxygen saturation (%).
Figure I3 Annual Atlantic zonal average (by one-degree squares) of oxygen saturation (%).
Figure I4 Annual Indian zonal average (by one-degree squares) of oxygen saturation (%).

APPENDIX J

- Figure J1a Global oxygen saturation (%) basin means (0-1000 m).
Figure J1b Global oxygen saturation (%) basin means (0-5500 m).
Figure J2a Pacific oxygen saturation (%) basin means (0-1000 m).
Figure J2b Pacific oxygen saturation (%) basin means (0-5500 m).
Figure J3a Atlantic oxygen saturation (%) basin means (0-1000 m).
Figure J3b Atlantic oxygen saturation (%) basin means (0-5500 m).
Figure J4a Indian oxygen saturation (%) basin means (0-1000 m).
Figure J4b Indian oxygen saturation (%) basin means (0-5500 m).
Table J1a Annual oxygen saturation (%) basin means and standard errors for the world ocean and Pacific Ocean as a function of depth.
Table J1b Annual oxygen saturation (%) basin means and standard errors for the Atlantic Ocean and Indian Ocean as a function of depth.

APPENDIX K

- Table K1 Area, volume, and percent volume contribution of each standard level to total basin volume mean, for the world ocean as a function of depth.
Table K2 Area, volume, and percent volume contribution of each standard level to total basin volume mean, for the Pacific Ocean as a function of depth.
Table K3 Area, volume, and percent volume contribution of each standard level to total basin volume mean, for the Atlantic Ocean as a function of depth.
Table K4 Area, volume, and percent volume contribution of each standard level to total basin volume mean, for the Indian ocean as a function of depth.
Table K5a Number of independent points (N_i) used in the standard error computations for the world ocean and Pacific Ocean.
Table K5b Number of independent points (N_i) used in the standard error computations for the Atlantic Ocean and Indian Ocean.
Table K6 Volume means of oxygen, Apparent Oxygen Utilization, and oxygen saturation for the major ocean basins and the volume of each basin.

APPENDIX L

- Figure L1 Winter (Jan.-Mar.) distribution of oxygen observations at the sea surface.
Figure L2 Winter (Jan.-Mar.) distribution of oxygen observations at 50 m depth.
Figure L3 Winter (Jan.-Mar.) distribution of oxygen observations at 100 m depth.

Preface

This atlas continues and extends an earlier work entitled *Climatological Atlas of the World Ocean* (Levitus, 1982). This earlier work has proven to be of great utility to the international oceanographic, climate research, and operational communities. In particular, the objectively analyzed fields of temperature and salinity have been used in a variety of ways. These include use as boundary and/or initial conditions in numerical ocean circulation models, for verification of numerical simulations of the ocean, as a form of "sea truth" for satellite measurements such as altimetric observations of sea surface height, and for planning oceanographic expeditions. We have expanded this earlier work to include chemical parameters such as phosphate, nitrate, and silicate because: 1) our belief that a comprehensive set of objectively analyzed parameter fields describing the state of the ocean, based on all existing oceanographic data, should be available as a matter of course to the international research community and 2) the immediate, compelling need for such analyses to study the role of biogeochemical cycles in determining how the earth's climate system works. For example, it is well known that the amount of carbon dioxide in the earth's atmosphere is expected to double during the next century. Regardless of one's scientific and/or political view of a possible "enhanced greenhouse warming" due to the increase of carbon dioxide, it is a necessity that the international scientific community have access to the most complete historical oceanographic data bases to study this problem, as well as other scientific and environmental problems.

The production of global analyses of oceanographic data is a major undertaking. Such work benefits from the input of many individuals and organizations. We have tried to structure the data sets and analyses that constitute this atlas in such a way as to encourage feedback from experts around the world who have knowledge that can improve future atlases. The production of works like this atlas series is becoming easier because of advances in computer hardware and software. These include: 1) the development of relatively inexpensive but powerful workstations that can be dedicated to data processing and analysis and 2) the development of high resolution printers and interactive graphics software that minimize the need for expensive, time consuming manual drafting and photographic processing. Because of the substantial increase in the historical oceanographic data bases expected over the next several years, the Ocean Climate Laboratory plans to update and expand this atlas series on a relatively frequent basis that will be determined by the accession of significant amounts of new data. We plan to publish volumes that focus on derived quantities, higher resolution analyses, and additional parameters such as chlorophyll, primary production, and plankton taxa and biomass.

The objective analyses in this atlas, and data on which they are based, are being made available internationally without restriction on various magnetic media as well as CD-ROMs. This is to insure the widest possible distribution.

In each acknowledgement section of this atlas series we have expressed our view that such series is only possible through international cooperation of scientists, data managers, and scientific administrators throughout the international community. I would also like to thank my co-authors, colleagues, and staff from the Ocean Climate Laboratory of NODC for their dedication to the project leading to publication of this atlas series. Their integrity and thoroughness have made possible this multi-volume atlas series. Oceanography is a field of increasing specialization, and it is my belief that the development of national and international oceanographic data archives is best performed by scientists who are actively working with the historical data. Margarita Conkright and Timothy Boyer receive my particular thanks.

Sydney Levitus
Director, Ocean Climate Laboratory
National Oceanographic Data Center
Washington, D.C.
March, 1994

Acknowledgements

The establishment of a research group at the National Oceanographic Data Center to focus on the preparation of research quality oceanographic data sets and their objective analyses sets has been made possible by a grant from the NOAA Climate and Global Change Program. Substantial amounts of historical oceanographic data used in this study were located and digitized (Data Archaeology and Rescue projects) with funding from the NOAA Climate and Global Change Program, the NOAA Environmental Services Data and Information Management Program, the National Science Foundation, and the Office of Naval Research.

The work described in this atlas was made possible by scientists, technicians, ships' crew, data managers, and science administrators from the international scientific community. This atlas represents the results of several different research/data management projects of the NODC Ocean Climate Laboratory at the National Oceanographic Data Center (NODC), Washington, D.C. The products in this atlas are all based on the master oceanographic data archives maintained by NODC/WDC-A as well as data acquired as a result of the NODC Data Archaeology and Rescue (NODAR) project and the IOC/IODE Global Oceanographic Data Archaeology and Rescue (GODAR) project. These archives and data sets exist because scientists of the international scientific community have submitted their data to national and regional data centers. In turn these centers have submitted data to the World Data Center system established under the International Council of Scientific Unions and the Intergovernmental Oceanographic Commission. This atlas and similar works would not exist without these international efforts. In particular we would like to thank data managers at these centers and the administrators and staff of these international organizations. The archiving of oceanographic data at international data centers means that the substantial expenditures in human and capital resources devoted to oceanographic measurement programs will be fully exploited, both for present and future scientific studies.

Although many data managers from the international community have been instrumental in the building of global oceanographic data bases we would like to thank in particular Harry Dooley of the International Council for Exploration of the Sea, Osamu Yamada, Director of the Japanese Oceanographic Data Center, Yuri Sychev of the Russian National Oceanographic Data Center, Hou Wen-Feng of the Chinese National Oceanographic Data Center, Shin Tani formerly of the Japanese Oceanographic Data Center, and Ronald Wilson of the Marine Environmental Data Service, Canada.

Jeff Burney provided excellent system administration and programming support. Daphne Johnson provided invaluable assistance in unpacking numerous data sets used in this project and preparing figures. Robert Gelfeld was instrumental in the acquisition of numerous data sets as part of the NODAR and GODAR Projects. Margarita Conkright provided assistance in the preparation of figures and of this atlas in general. Grigory Isayev and Linda Stathoplos helped with technical editing of the manuscript. Our colleagues at NODC/WDC-A provided support for various data management projects related to this atlas. Jennifer Campbell helped in preparing the manuscript for publication. The support of Gregory Withee and Bruce Douglas, former and present directors of NODC is appreciated. Management support by Dave Goodrich of the NOAA Office of Global Programs is appreciated.

We also would like to thank Eric Shulenberger, Joe Reid, and Arnold Mantyla for reviewing the manuscript version of this atlas and providing comments that have led to substantial improvements in the text.

The data sets and products represented by this atlas are distributed internationally without restriction in accordance with U.S. Climate and Global Change as well as ICSU/IOC data management policies in support of Global Change Research.

WORLD OCEAN ATLAS, 1994: VOLUME 2, OXYGEN

Sydney Levitus and Timothy Boyer
National Oceanographic Data Center
Washington, D.C.

ABSTRACT

This atlas contains maps of dissolved oxygen, oxygen saturation, and Apparent Oxygen Utilization at selected standard levels of the world ocean on a one-degree grid. The fields used to generate these maps were computed by objective analyses of historical data. Maps for all-data annual and seasonal compositing periods are presented. Data distribution maps are presented for various compositing periods. Basin zonal averages and basin volume averages are computed from these objectively analyzed fields and presented in the form of figures and tables.

1. INTRODUCTION

The format of this atlas, as well as some of the text, follow Levitus (1982). This atlas is an analysis of all historical oxygen data available from the National Oceanographic Data Center (NODC), Washington, D.C., plus data gathered as a result of two data management projects: the NODC Oceanographic Data Archaeology and Rescue (NODAR) project and the Intergovernmental Oceanographic Commission (IOC) Global Oceanographic Data Archaeology and Rescue (GODAR) project. Data used here have been analyzed in a consistent, objective manner on a one-degree latitude-longitude grid at standard oceanographic analysis levels between the surface and ocean bottom or to a maximum depth of 5500m. The procedures used are similar, but not identical to, the analyses presented by Levitus (1982). Annual and seasonal analyses have been computed for dissolved oxygen, oxygen saturation, and Apparent Oxygen Utilization. The present analyses and statistical information are primarily intended for use in the study of the role of the world ocean as part of the earth's climate system.

Objective analyses shown in this atlas are limited by the nature of the data base (non-synoptic, scattered in space),

characteristics of the objective analysis techniques, and the grid used. These limitations and characteristics will be discussed below.

With the additional data made available since Levitus (1982), we have now been able to expand this earlier work to include seasonal analyses of oxygen. However, even with these additional data, we are still hampered in a number of ways by a lack of data. Because of the lack of data, we are forced to examine the annual cycle by compositing all data regardless of the year of observation. In some areas, quality control is made difficult by the limited number of data. Data may exist in an area for only one season, thus precluding any representative annual analysis. In some areas there may be a reasonable spatial distribution of data points on which to base an analysis, but there may be only a few (perhaps only one) datum in each one-degree square.

2. DATA AND DATA DISTRIBUTION

Data sources and quality control procedures are described

below. Because quality control procedures are so important, a technical report has been prepared fully describing these procedures (Boyer and Levitus, 1994).

2.1 Data sources

The Station Data used in this project were obtained from the National Oceanographic Data Center (NODC), Washington, D.C. and represent all the data available in the Oceanographic Station Data (SD) file as of the first quarter of 1993 (NODC, 1993), plus data gathered as a result of the NODAR and GODAR projects (Levitus *et al.*, 1994a) that have not yet been archived in the NODC digital archives. In addition, the collection of international oceanographic profiles that comprise the Hydrographic Atlas of the Southern Ocean developed by Olbers *et al.* (1992) at the Alfred Wegener Institute for Polar and Marine Research were included.

Figures 1-3 and Table 1 show the global distributions of oxygen measurements as a function of time and at selected depths. Shown in Figure 3 are the number of observed data points that occur in the depth range centered around each standard level. The depth range for the sea surface is 0-5 m. At all other standard levels, the depth range is defined as the region between the midpoints of the standard level being considered and the adjacent standard levels above and below. Appendix A shows the geographic distribution of historical oxygen observations as a function of depth. Appendix L shows the distribution of historical oxygen observations as a function of depth for individual seasons.

One must understand our terms "standard level data" and "observed level data" to understand the various data distribution and summary figures and tables we present in this atlas. We refer to the actual measured value of an oceanographic parameter *in situ* as an "observation," and to the depth at which such a measurement was made as "observed level depth." We may refer to such data as "observed level data." Before the advent of oceanographic instrumentation that measure at high frequencies in the vertical, oceanographers often attempted to make measurements at selected "standard levels" in the water column. Sverdrup *et al.* (1942) presented the suggestions of the International Association of Physical Oceanography (IAPSO) as to which depths oceanographic measurements should be made or interpolated to for analysis. Different nations or institutions have "supersets" of standard level observation (e.g. NODC, 1993). For many purposes, including here, observed level data are interpolated to standard observation levels, if they do not occur exactly at

a standard observation level. In contrast to Levitus (1982), we have used counts of "observed level values" wherever possible when summarizing the historical data used in this atlas. The distinction may seem minor, but in fact the criteria used to determine whether observed level data are suitable for use in interpolating to standard levels are not trivial. For example, one does not wish to use an observed level value at 5000 m depth to determine an interpolated standard level value at 20 m depth. Section 3.1 discusses this further.

2.2 Data quality control

Quality control of the data is a major task whose difficulty is directly related to lack of data (in some areas) upon which to base statistical checks. Consequently certain empirical criteria were applied, and as part of the last processing step, subjective judgment was used. Individual data, and in some cases entire profiles or cruises, have been flagged because these data produced features that were judged to be non-representative or in error. As part of our work, we will make available both observed level profiles as well as standard level profiles with various quality control flags applied. Our knowledge of the variability of the world ocean now includes a greater appreciation and understanding of the ubiquity of eddies, rings, and lenses in some parts of the world ocean as well as interannual and interdecadal variability of water mass properties. Therefore, we have simply flagged data, not eliminated them. Thus individual investigators can make their own decision regarding the representativeness or correctness of the data. Investigators studying the distribution of features such as eddies will be interested in those data that we may regard as unrepresentative for our purpose here.

2.2a Duplicate elimination

Because data are received from many sources, all data files were checked for the presence of exact replicates. Approximately 20,000 Station Data profiles in the NODC Station Data File were found to be exact replicates of other profiles in this file. All but one profile from each set of replicate profiles were eliminated as the first step of our processing. All data sets used that were not part of the NODC Station Data file were checked for duplicates against the NODC Station Data file. All replicates were eliminated from further use.

2.2b Range checking

Range checking was performed on all data as a first error check to eliminate the relatively few data that seemed to be grossly in error. Range checks were prepared for individual regions of the world ocean in contrast to Levitus' (1982) use of one range check for the entire world ocean for each parameter. Future work will include ranges for different basins by individual seasons. Boyer and Levitus (1994) detail the quality control procedures and include tables showing the ranges we selected for each basin

2.2c Statistical checks

Statistical checks were performed to eliminate outliers as follows. All data for each parameter (irrespective of seasons), at each standard level, were averaged by five-degree squares to produce a record of the number of observations, mean, and standard deviation in each square. Below 50 m depth, a three-standard-deviation criterion was used to flag data and eliminate individual observations from further use in our objective analyses. Above 50 m depth, a five-standard-deviation criterion was used in five-degree squares that contained any land area. In selected five degrees squares that came close to land areas, a four standard-deviation check was used. In all other squares a three-standard-deviation criterion was used with the following exceptions. For those data that occurred at or deeper than the standard level depth in the one-degree square in which the profile was observed, a four standard deviation criteria was used. For those data in a one-degree square that were measured at a depth deeper than the depth of any adjacent one-degree square, a four-standard-deviation check was used.

The reason for the weaker criterion in coastal and near-coastal regions is the exceptionally large variability in the coastal five-degree square statistics for some parameters. Frequency distributions of some parameters in some coastal regions are observed to be skewed or bimodal. Thus to avoid eliminating possibly good data in highly variable environments, the standard deviation criteria were weakened.

The total number of oxygen measurements in each cast, as well as the total number of observations exceeding the criterion, were recorded. If more than two observations in a cast were found to exceed the standard deviation criterion, then the entire cast was eliminated. This check was imposed after tests indicated that surface data from particular casts (which upon inspection appeared to be

erroneous) were being eliminated but deeper data were not. Other situations were found where erroneous data from the deeper portion of a cast were eliminated, while near-surface data from the same cast were not eliminated because of larger natural variability in surface layers. One reason for this was the decrease of the number of observations with depth and the resulting change in sample statistics. The standard-deviation check was applied twice to the data set.

In summary, first the five-degree square statistics were computed, and the elimination procedure described above was used to provide a preliminary data set. Next, new five-degree-square statistics were computed from this preliminary data set and used with the same statistical check to produce a new, "clean" data set. The reason for applying the statistical check twice was to eliminate, in the first round, any grossly erroneous or non-representative data from the data set that would artificially increase the variances. The second check then should be more effective in eliminating smaller, but probably still erroneous or non-representative observations.

2.2d Subjective elimination of data

The data were averaged by one-degree squares for input to the objective analysis program. After initial objective analyses were computed, the input set of one-degree means still contained suspicious data contributing to unrealistic distributions, yielding intense bull's-eyes or gradients. Examination of these features indicated that some of them were due to particular oceanographic cruises. In such cases data from an entire cruise were eliminated from further use by setting a flag on each profile from the cruise.

2.2e Representativeness of the data

Another quality control issue is data representativeness. The general paucity of data forces us to composite all historical data to produce "climatological" fields. In a given one-degree square, there may be data from a month or season of one particular year, while in the same or a nearby square there may be data from an entirely different year. If there is large interannual variability in a region where scattered sampling in time has occurred, then one can expect the analysis to reflect this. Because the observations are scattered non-randomly with respect to time, except for a few limited areas, the results cannot, in a strict sense, be considered a true long-term climatological average.

We present smoothed analyses of historical means, based (in certain areas) on relatively few observations. We believe, however, that useful information about the oceans can be gained through our procedures and that the large-scale features are representative of the real ocean. We believe that, if a hypothetical global synoptic set of ocean data (temperature, salinity, or oxygen) existed, and one were to smooth this data to the same degree as we have smoothed the historical means overall, the large-scale features would be similar to our results. Some differences would certainly occur because of interannual to decadal-scale variability. As more data are added to the historical archives, we will be able to evaluate this variability on basin and gyre scales following the studies of Levitus (1989a,b,c; 1990) and Levitus *et al.* (1994c).

To clarify discussions of the amount of available data, quality control techniques, and representativeness of the data, the reader should examine in detail the maps showing the distribution of data (Appendices A and L). These maps are provided to give the reader a quick, simple way of examining the historical data distributions. Basically, the data diminish in number with increasing depth and latitude. In the upper ocean, the all-data annual mean distributions are quite good for defining large-scale features, but for the seasonal periods, the data base for some regions is inadequate. With respect to the deep ocean, in some areas the distribution of observations may be adequate for some diagnostic computations but inadequate for other purposes. Obviously if an isolated deep basin or some region of the deep ocean has only one observation, then no horizontal gradient computations are meaningful. However useful information is provided by the observation in the computation of other quantities (e.g., a volumetric mean over a major ocean basin).

2.2f Calculation of derived quantities

Calculation of oxygen saturation was per Garcia and Gordon (1992). Apparent Oxygen Utilization (AOU) was computed as the difference of the oxygen content of a sea water parcel at 100 per cent saturation minus the observed oxygen content.

3. DATA PROCESSING PROCEDURES

3.1 Vertical interpolation to standard levels

Vertical interpolation of observed level data to standard

levels followed procedures in UNESCO (1991). These procedures are in part based on the work of Reiniger and Ross (1968). Four observed level values surrounding the standard level values were used, two values from above the standard level and two values below the standard level. Paired parabolas were generated via Lagrangian interpolation. A reference curve was fitted to the four data points and used to define unacceptable interpolations caused by "overshooting" in the interpolation. When a spurious extremum could not be eliminated using this technique, linear interpolation was used. When there were too few data points above or below the standard level to apply the Reiniger and Ross technique, we used a three-point Lagrangian interpolation. If three points were not available (either two above and one below or vice-versa), we used linear interpolation. In the event that an observation occurred exactly at the depth of a standard level, then a direct substitution was made. Table 2 provides the range of acceptable distances for which observed level data could be used for interpolation to a standard level. The criteria were a function of depth. The criteria for the "outside" points were the same as used by NODC in their three-point Lagrangian interpolation and by Levitus (1982). The criteria for the "inner" points was much more restrictive and resulted in fewer standard level data values compared to the NODC and Levitus (1982) criteria. Future criteria might depend on the geographic location of the profile as well as the time of year.

The data summaries in Table 1 and all other such counts represent the observed level data. These are counts of observed level data that occur within a depth interval around each standard level. This differs from the statistics presented by Levitus (1982) who presented counts of interpolated standard level data.

3.2 Methods of analysis

3.2a Overview

An objective analysis scheme of the type described by Barnes (1973) was used to produce the fields shown in this atlas. This scheme had its origins in the work of Cressman (1959) and Barnes (1964). The Barnes (1973) scheme requires only one "correction" to the first guess field at each grid point in comparison to the successive correction method of Cressman and Barnes (1964). For completeness we derive the weight function and response function per Barnes (1964) and then per Barnes (1973).

Inputs to the analysis scheme were observed one-degree

square means of data at standard levels (for whatever period and parameter being analyzed), and a first-guess value for each square. For instance, one-degree square means for our annual analysis were computed using all available data regardless of date of observation. For July, we used all historical July data regardless of year of observation.

Analysis was the same for all standard depth levels. Each one-degree square value was defined as being representative of its square. The 360x180 gridpoints are located at the intersection of half-degree lines of latitude and longitude. An influence radius was then specified. At those grid points where there was an observed mean value, the difference between the mean and the first-guess field was computed. Next, a correction to the first-guess value at all gridpoints was computed as a distance-weighted mean of all gridpoint difference values that lie within the area around the gridpoint defined by the influence radius. Mathematically, the correction factor derived by Barnes (1964) is given by the expression

$$C_{ij} = \frac{\sum_{s=1}^n W_s Q_s}{\sum_{s=1}^n W_s} \quad (1)$$

in which

C_{ij} = the correction factor at gridpoint coordinates (i,j)

(i,j) = coordinates of a gridpoint in the east-west and north-south directions, respectively

n = the number of observations that fall within the area around the point i,j defined by the influence radius

Q_s = the difference between the observed mean and the first guess at the Sth point in the influence area

W_s = exp (-E r² R⁻²) for r < R

W_s = 0 for r > R

r = distance of the observation from the gridpoint

R = influence radius

E = 4

The derivation of the weight function, W_s, will be presented in the following section. At each gridpoint we computed an analyzed value G_{ij} as the sum of the first guess, F_{ij} and the correction C_{ij}. The expression for this is

$$G_{ij} = F_{ij} + C_{ij} \quad (2)$$

If there were no data points within the area defined by the influence radius, then the correction was zero, the first-guess field was left unchanged, and the analyzed value was simply the first-guess value. This correction procedure was applied at all gridpoints to produce an analyzed field. The resulting field was first smoothed with a median filter (Tukey, 1974; Rabiner *et al.*, 1975) and then smoothed with a five-point smoother of the type described by Shuman (1957).

The analysis scheme is based on the work of several researchers analyzing meteorological data. Bergthorsson and Doos (1955) computed corrections to a first-guess field using various techniques: one assumed that the difference between a first-guess value and an analyzed value at a gridpoint was the same as the difference between an observation and a first-guess value at a nearby observing station. All the observed differences in an area surrounding the gridpoint were then averaged and added to the gridpoint first guess value to produce an analyzed value. Cressman (1959) applied a distance-related weight function to each observation used in the correction in order to give more weight to observations that occur closest to the gridpoint. In addition, Cressman introduced the method of performing several iterations of the analysis scheme using the analysis produced in each iteration as the first-guess field for the next iteration. He also suggested starting the analysis with a relatively large influence radius and decreasing it with successive iterations so as to analyze smaller scale phenomena with each pass.

Sasaki (1960) introduced a weight function that was specifically related to the density of observations, and Barnes (1964, 1973) extended the work of Sasaki. The weight function of Barnes (1973) has been used here. The derivation of the weight function we used which we present for completeness, follows the work of Barnes (1973).

The objective analysis scheme we used is in common use by the meso scale meteorological community. Several studies of objective analysis techniques have been made. Achtemeier (1987) examined the "concept of varying influence radii for a successive corrections objective analysis scheme." Seaman (1983) compared the "objective

analysis accuracies of statistical interpolation and successive correction schemes." Smith and Leslie (1984) performed an "error determination of a successive correction type objective analysis scheme." Smith *et al.* (1986) made "a comparison of errors in objectively analyzed fields for uniform and non-uniform station distribution."

3.2b Derivation of Barnes (1964) weight function

The principle upon which Barnes' (1964) weight function is derived is that "the two-dimensional distribution of an atmospheric variable can be represented by the summation of an infinite number of independent harmonic waves, that is, by a Fourier integral representation". If $f(x,y)$ is the variable, then in polar coordinates (r,θ) , a smoothed or filtered function $g(x,y)$ can be defined:

$$g(x,y) = \frac{1}{2\pi} \int_0^{2\pi} \int_0^{\infty} \eta f(x+r\cos\theta, y+r\sin\theta) d\theta dr$$

$$d\left(\frac{r^2}{4K}\right) d\theta \quad (3)$$

in which r is the radial distance from a gridpoint whose coordinates are (x,y) . The weight function is defined as

$$\eta = \exp(-r^2/4K) \quad (4)$$

which resembles the Gaussian distribution. The shape of the weight function is determined by the value of K , which depends on the distribution of data. The determination of K follows. The weight function has the property that

$$\frac{1}{2\pi} \int_0^{2\pi} \int_0^{\infty} \eta d\left(\frac{r^2}{4K}\right) d\theta dr = 1. \quad (5)$$

This property is desirable because in the continuous case (3) the application of the weight function to the distribution $f(x,y)$ will not change the mean of the distribution. However, in the discrete case (1), we only sum the contributions to within the distance R . This introduces an error in the evaluation of the filtered function, because the condition given by (5) does not

apply. The error can be pre-determined and set to a reasonably small value in the following manner. If one carries out the integration in (5) with respect to θ , the remaining integral can be rewritten as

$$\int_0^R \eta d\left(\frac{r^2}{4K}\right) + \int_R^{\infty} \eta d\left(\frac{r^2}{4K}\right) = 1. \quad (6)$$

Defining the second integral as ϵ yields

$$\int_0^R \exp\left(-\frac{r^2}{4K}\right) d\left(\frac{r^2}{4K}\right) = 1 - \epsilon. \quad (7)$$

in which

$$\epsilon = \exp(-R^2/4K).$$

Levitus (1982) chose $\epsilon = 0.02$, which implies with respect to (6) the representation of 98 percent of the influence of any data around the gridpoint in the area defined by the influence radius, R . In terms of the weight function used in the evaluation of (1) this choice leads to a value of $E=4$ since

$$E = R^2/4K = -\ln \epsilon.$$

The choice of ϵ and the specification of R determine the shape of the weight function.

Barnes (1964) proposed using this scheme in an iterative fashion similar to Cressman (1959). Levitus (1982) used a four iteration scheme with a variable influence radius for each pass.

3.2c Derivation of Barnes' (1964) response function

It is desirable to know the response of a data set to the interpolation procedure applied to it. Following Barnes (1964) we let

$$f(x) = A \sin(ax) \quad (8)$$

in which $a = 2\pi/\lambda$ with λ being the wavelength of a particular Fourier component, and substitute this function into equation (3) along with the expression for $\hat{\eta}$ in equation (4). Then

$$g(x) = D (A \sin(ax)) = D f(x) \quad (9)$$

in which

$$D = \exp(-\pi^2 R^2 / 4\lambda^2).$$

D is the response function for one application of the analysis. The phase of each Fourier component is not changed by the interpolation procedure. The results of an analysis pass are used as the first guess for the next analysis pass in an iterative fashion. The response function after N iterations as derived by Barnes (1964) is

$$g_N(x) = f(x)D \sum (1-D)^{N-1}. \quad (10)$$

Equation (10) differs trivially from that given by Barnes. The difference is due to the fact that our first-guess field was defined as a zonal average, annual mean, or seasonal mean, whereas Barnes used the first application of the analysis as a first guess. Barnes (1964) also showed that applying the analysis scheme in an iterative fashion will result in convergence of the analyzed field to the observed data field. However, it is not desirable to approach the observed data too closely, because at least seven or eight gridpoints are needed to represent a Fourier component.

The response function given in (10) is useful in two ways: it is informative to know what Fourier components make up the analyses, and the computer programs used in generating the analyses can be checked for correctness by comparison with (10).

3.2d Derivation of Barnes (1973) weight function

Barnes (1973) showed how a nearly equivalent analysis (with respect to the response function) could be performed with just one iteration, assuming a first guess field is provided. We use this one-pass scheme in our present analyses. Derivation of the weight function for this scheme is provided (below) after the derivation of the response function in the following section. Following Barnes (1973), equation (9) can be rewritten as

$$g_0(x,y) = D_0 f(x,y). \quad (11)$$

The subscript nought denotes the first pass through the data with weight function

$$\hat{\eta}_0 = \exp(-r^2/4K_0). \quad (12)$$

Using the results of the initial analysis as a first guess for the second iteration through the data, we add the residual field of the second pass analysis to the first guess provided by the first iteration. We write this as

$$g_1(x,y) = g_0(x,y) + [f(x,y) - g_0(x,y)] D_1 \quad (13)$$

where D_1 is the response resulting from application of the weight function

$$\hat{\eta}_1 = \exp(-r^2/4k_1); \quad k_1 = \gamma k_0 \quad \text{and} \quad \gamma > 0 \quad (14)$$

$$D_1 = \exp(-a^2 k_1) = \exp(-a^2 k_0) = D_0^{-\gamma}. \quad (15)$$

Substituting (15) and (11) into (13) yields

$$g_1(x,y) = f(x,y)D_0 (1 + D_0^{-\gamma-1} - D_0^{-\gamma}). \quad (16)$$

The new response function is

$$D' = D_0 (1 + D_0^{-\gamma-1} - D_0^{-\gamma}). \quad (17)$$

The value $k_1 = \gamma k_0$ is chosen to produce a desired response function. In our analyses a value of $k_1 = 0.8$ was used. This choice leads to the response function given in

Table 3.

There are several advantages of a one-pass interpolation analysis. The saving of computer time is an obvious advantage. A more important advantage is that statistical analysis of the analyzed fields becomes much simpler.

3.2e Choice of response function

The distribution of observations (see appendices) at different depths and for the different averaging periods, not regular in space or by season. At one extreme, regions exist in which every one-degree square contains data and no interpolation needs to be performed. At the other extreme are regions in which few data exist. Thus with variable data spacing the average separation distance between gridpoints containing data is a function of geographical position and averaging period. However, if we computed and used a different average separation distance for each parameter at each depth and each averaging period, we would be generating analyses in which the wavelengths of observed phenomena might differ from one depth level to another and from one season to another. We chose instead to use a fixed influence radius of 555 km which allows us to analyze each parameter at every depth and season in exactly the same way.

Inspection of (1) shows that the difference between the analyzed field and the first guess at any gridpoint is proportional to the sum of the weighted differences between the observed mean and first-guess at all gridpoints containing data within the influence area.

The reason for using the five-point smoother and the median smoother is that our data are not evenly distributed in space. As the analysis moves from regions containing data to regions devoid of data, small-scale discontinuities may develop. The five-point and median smoothers are used to eliminate these discontinuities. The five-point smoother does not affect the phase of the waves in the data.

At gridpoints where no observed data points fall within the influence area, one could expand the influence radius until some minimum number of data points were found. We did not use this procedure, because it implies an analysis with different maximum length scales in different regions, and we wish to minimize such differences.

The response function for the analyses presented in this atlas is given in Table 3. The response function represents

the smoothing inherent in the objective analysis described above plus the effects of one application of the five-point smoother and one application of a five-point median smoother.

3.2f First guess field determination

There are gaps in the data coverage and, in some parts of the world ocean, there exist adjacent basins whose water mass properties are individually nearly homogeneous but have distinct basin-to-basin differences. Spurious features can be created when an influence area extends over two basins of this nature. Our choice of first-guess field attempts to minimize the creation of these features.

To provide a first guess field for the annual analysis at any standard level, we first zonally averaged the observed data in each one-degree latitude belt by individual ocean basins. In the work of Levitus (1982), the Mediterranean and Red Seas were treated as individual basins and the Venezuela Basin and the Sulu Sea were treated as individual basins below their sill depths. The Norwegian Sea and Arctic Ocean were treated separately below the sill depth of the Greenland-Iceland-Shetland ridge. In the present work, additional basins have also been defined.

To avoid the problem of the influence region extending across land or sills to adjacent basins, the objective analysis program uses basin "identifiers" to avoid the use of data from adjacent basins. Table 4 lists these basins and the depth at which no exchange of information between basins is allowed during the objective analysis of data, i.e., "depths of mutual exclusion." Some regions are nearly, but not completely, isolated topographically. Because some of these nearly isolated basins have water mass properties that are different from surrounding basins, we have chosen to treat these as isolated basins as well. Not all such basins have been identified because of the complicated structure of the sea floor.

The zonal average computed for every one-degree belt in every individual ocean basin was used as the first guess for all one-degree squares in the belt. The reason for computing a separate first guess in each individual basin can be explained with the aid of equations (1) and (2). We

have at any grid point (i,j) an analyzed value as defined by

$$G_{ij} = F_{ij} + \frac{\sum_{s=1}^n (W_s Q_s)}{\sum_{s=1}^n (W_s)} \quad (18)$$

For simplicity, we discuss the case in which only one observed data point falls within the influence area. The coordinates of this point will be denoted by i',j' on our grid. If we let OB_{ij} denote the observed one-degree square mean at this point then (18) becomes

$$G_{ij} = F_{ij} + (OB_{i',j'} - FG_{i',j'}) \quad (19)$$

Thus for this case the difference between the analyzed point and the first guess at point (i,j) is assumed to equal the first-guess at the point (i',j'). If the observed mean at a gridpoint is equal to the first-guess at that gridpoint, then the correction is zero, and this gridpoint will affect no other gridpoint. For situations where we have adjacent basins with individually nearly homogeneous properties (those not identified in Table 4), then defining a separate first-guess field for each basin means that the observed means in each basin are closer to their first-guess field than if this separation of basins had not been performed. Thus when the influence area extends across basins the corrections are relatively small.

Iteration provided first guess fields for seasonal and monthly analyses. Annual analyses were used as first-guess fields for each of the four seasonal analyses. For oxygen, a new annual analysis was computed as the mean of the four seasonal analyses, and then used as the first guess in a reanalysis of seasonal oxygen data. This procedure produces slightly smoother annual means. More importantly we recognize that fairly large data-void regions exist, in some cases to such an extent that a seasonal or monthly analysis in these regions is not meaningful. We are interested in computing integral quantities such as oxygen storage that are deviations from annual means. Geographic distribution of observations for the all-data annual periods (see appendices) is excellent for upper layers of the ocean. By using an all-data annual mean, first-guess field regions where data exists for only one season or month will show no contribution to the annual cycle. By contrast, if we used a zonal average for each season or month, then, in those latitudes where gaps exist, the first-guess field would be heavily biased by the few

data points that exist. If these were anomalous data in some way, an entire basin wide belt might be affected.

One advantage of producing "global" fields for a particular compositing period (even though some regions are data void) is that such analyses can be modified by investigators for use in modelling studies. For example, England (1992) noted that the salinity distribution produced by Levitus (1982) for the Antarctic is too low (due to a lack of winter data for the Southern Hemisphere) to allow for the formation of Antarctic Intermediate Water in an ocean general circulation model. By increasing the salinity of the "observed" field the model was able to produce this water mass.

3.3 Choice of objective analysis procedures

Optimum interpolation (Gandin, 1963) has been used by some investigators to objectively analyze oceanographic data. We recognize the power of this technique but have not used it to produce analyzed fields. As described by Gandin (1963), optimum interpolation is used to analyze synoptic data using statistics based on historical data. In particular, second-order statistics such as correlation functions are used to estimate the distribution of first order parameters such as means. We attempt to map most fields in this atlas based on relatively sparse data sets. By necessity we must composite all data regardless of year of observation, to have enough data to produce a global, hemispheric, or regional analysis for a particular month, season, or even yearly. Because of the paucity of data, we prefer not to use an analysis scheme that is based on second order statistics. In addition, as Gandin has also noted, there are two limiting cases associated with optimum interpolation. The first is when a data distribution is dense. In this case the choice of interpolation scheme makes little difference. The second case is when data are sparse. In this case an analyses scheme based on second order statistics is of questionable value. For additional information on objective analysis procedures, see Thiebaux and Pedder (1987) and Daley (1991).

3.4 Choice of spatial grid

We use the one-degree grid of Levitus (1982) which is based on the ocean topography defined by Smith *et al.*, (1966) as our spatial grid. We desire to build a set of climatological analyses that are identical in all respects for all parameters including relatively data sparse parameters such as nutrients. This provides investigators with a

consistent set of analyses to work with. As more data are received at NODC/WDC-A, we will be able to produce higher resolution climatologies for certain parameters.

4. RESULTS

4.1 Annual mean oxygen parameters at standard levels

4.1a *Explanation of standard level figures*

All figures showing standard level analyses in this atlas series use similar symbols for displaying information. Continents are indicated as solid - black areas. Ocean areas shallower than the standard depth level being displayed are gray. Negative regions are dot stippled. Gridpoints for which there were less than three one-degree-square values available to "correct the first guess are indicated by an X. Dashed lines represent non-standard contours. "H" and "L" indicate locations of the absolute maximum and minimum of the entire field. All figures were computer drafted. As a result some contours are not labelled. For clarity we use dark lines for every fourth or fifth contour in the standard level fields.

4.1b *Standard level analyses*

Global distributions of annual mean dissolved oxygen, Apparent Oxygen Utilization, and oxygen saturation, at standard analysis levels are presented in Appendices B, E, and H, respectively. Seasonal analyses of these three parameters are presented in Appendices M, O, and Q respectively. Seasonal mean minus annual mean difference fields of these parameters are presented in Appendices N, P, and R respectively. These seasonal fields allow investigators to quantify some annual biogeochemical cycles of the world ocean for the first time. The annual cycle of oxygen is related to annual cycles of productivity in the upper ocean, meteorological forcing and solar radiation. Redfield (1948) estimated of the flux of oxygen across the air-sea interface. Recently Keeling and Shertz (1992) described the seasonal cycle of oxygen in the atmosphere. Based on their measurements and the results shown in this atlas it is now possible to estimate, albeit crudely, the flux of oxygen across the air-sea interface. This is not only a scientific problem in its own right but also a means to understanding the seasonal variability of the earth's biogeochemical cycles. Of all scales of oceanic

variability, the seasonal cycle may be the largest signal for most of the world ocean.

Perhaps the most interesting feature we find involves the seasonal cycle of oxygen saturation. Specifically it occurs in the region poleward of 15 degrees latitude in both hemispheres of the Atlantic and Pacific Oceans, and in the southern hemisphere portion of the Indian Ocean in the seasonal minus annual percent oxygen saturation fields (Appendix R). During winter, the difference fields are negative in the upper 50-100 m of the water column. Below this depth, extending to about 200-300 m depth, the differences are positive. The reverse pattern holds true for the summer. The phase of the annual cycle in the upper ocean is consistent with changes in the solubility of oxygen with temperature. During periods of colder temperature the solubility of oxygen in seawater is greater and hence the percent oxygen saturation should decrease, assuming no other factors are involved. This phase is also consistent with a smaller biological production of oxygen due to reduced light levels during winter. The phase of the seasonal cycle below the depth of the phase change may be related to the depth of the seasonal mixed layer and biological production. Examination of the basin zonal averages of these seasonal difference fields and computation of annual range (Levitus *et al.*, 1994b) indicates that the seasonal cycle of oxygen extends down to several hundred meters depth in mid latitudes. An earlier attempt to describe the seasonal cycle of oxygen was by Muromtsev (1958).

4.2 Basin zonal averages

Basin zonal averages were computed using the definition of basins as shown in Fig. 4. Appendices C, F, and I show the basin zonal averages of oxygen, Apparent Oxygen Utilization, and percent oxygen saturation, respectively.

4.3 Basin mean profiles and volume means

Area-weighted basin means of oxygen parameters have been computed for the world ocean for each of the major ocean basin and for the northern and southern hemisphere portions of these basins and are presented as a function of depth in Appendices D, G, and J. These means and associated standard errors are also presented in tabular form in the same appendices. The area and volume of each standard level over which the means are computed is given in Appendix K. The percentage contribution that each standard level contributes to the volume of each basin is given, as well as the number of independent points used

in the standard error computation. Basin volume-weighted means and the total volume in each basin are also presented in Appendix K. Of course one can construct and display the basin-wide averages in a number of ways to serve various purposes. The tabulations allow users to graph the information and perform computations in any desired format.

The formula for defining an area weighted mean of some parameter X over the N ocean one-degree squares in a particular region or basin is

$$\bar{X}_N = \frac{\sum_{n=1}^N X_n A_n}{\sum_{n=1}^N A_n} \quad (20)$$

in which X_n represents the value of the parameter at the n^{th} one-degree square of the region, and A_n represents the area of the n^{th} one-degree square in the region. Computation of volume means uses formula (20) with the volume V_n replacing the area element A_n . The volume of a one-degree square box at any particular standard level is defined as follows. Excluding the sea surface and deepest standard level occurring at any one-degree square water column, the depth range Δz_k , through which a volume is computed for any standard level (denoted by k), is given as

$$\Delta z_k = 0.5 [z_{k+1} - z_{k-1}] \quad (21)$$

in which z_{k+1} is the depth of the first standard level deeper than standard level k , and z_{k-1} is the depth of the first standard level shallower than standard level k . The volume of the sea surface standard level is taken over the 0-5 m depth interval. The depth range through which a volume is computed for the deepest standard level is given as

$$\Delta z_k = 0.5 [z_k - z_{k-1}] . \quad (22)$$

The standard error (S.E.) of each basin mean is computed as follows. The area-weighted root-mean-square deviation of all gridpoint values is computed (denoted as σ). The total area of the standard level within the basin is computed and divided by the area defined by the influence radius of the objective analysis. This area is given as πR^2 in which $R=555$ km. The quotient yields a value, N_p , which is used as the number of independent points in

estimating the standard error as

$$\text{S.E.} = \sigma / (N_p)^{1/2} .$$

5. SUMMARY

In the preceding sections we have described the results of a project to objectively analyze all historical oxygen data archived at the National Oceanographic Data Center, Washington, D.C., plus additional data gathered as a result of the NODC and IOC data archaeology and rescue projects, that have not yet been incorporated into the NODC archive.

One advantage of the analysis techniques used in this atlas is that we know the amount of smoothing by objective analyses as given by the response function in Table 2. We believe this to be an important parameter in constructing and describing a climatology of any geophysical parameter. Particularly when computing anomalies from a standard climatology, it is important that the synoptic field be smoothed to the same extent as the climatology, to prevent generation of spurious anomalies simply through differences in smoothing. A second reason is that purely diagnostic computations require a minimum of seven or eight gridpoints to represent any Fourier component with accuracy. Higher order derivatives will require more smoothing.

We have attempted to create objectively analyzed fields and data sets that can be used as a "black box." We emphasize that some quality control procedures used are subjective. For those users who wish to make their own choices, all the data used in our analyses are available both at standard depth levels as well as observed depth levels. The results presented in this atlas show some features that are suspect and may be due to nonrepresentative or incorrect data that were not eliminated by the quality control techniques used. Although we have attempted to eliminate as many of these features as possible some obviously remain. Some may eventually turn out not to be artifacts but rather to represent real features, as yet undescribed.

6. FUTURE WORK

Additional studies are in progress to describe the seasonal cycle of oxygen and related parameters (Levitus *et al.* 1994b). Oxygen is the only oceanographic parameter, other than temperature and salinity, for which we have enough data to describe the seasonal cycle. Hence the seasonal oxygen cycle occupies a potentially important role in understanding oceanic biogeochemical cycles on basin and seasonal scales. The clear seasonal cycle documented in this atlas occurs in each major ocean basin and reverses sign at about 100 m depth. It is strong evidence that similar factors are at work in each basin. This phenomenon should allow us to learn a great deal about the processes that drive it.

The acquisition of additional oxygen data will allow for a more detailed description of the seasonal and monthly cycles. Our analyses will be updated when justified by additional observations.

30 ΔX	0.907
24 ΔX	0.857
20 ΔX	0.801
18 ΔX	0.759
15 ΔX	0.671
12 ΔX	0.532
10 ΔX	0.397
9 ΔX	0.315
8 ΔX	0.226
6 ΔX	0.059
5 ΔX	0.019
4 ΔX	2.23x10 ⁻³
3 ΔX	1.90x10 ⁻⁴
2 ΔX	5.30x10 ⁻⁷

* For $\Delta X = 111$ km

Table 4. Basin identifiers and depths of "mutual exclusion" used in this study

Basin	Depth (m)	Basin	Depth (m)
Atlantic Ocean	---	Pacific Ocean	---
Indian Ocean	---	Mediterranean Sea	---
Baltic Sea	0	Black Sea	0
Red Sea	0	Persian Gulf	0
Hudson Bay	0	Southern Ocean	---
Arctic Ocean (Bering)	0	Sea of Japan	125
Kara Sea	200	Sulu Sea	500
Arctic Ocean (Atlantic)	600	Baffin Bay	700
East Mediterranean	1000	West Mediterranean	1000
Sea of Oshkotsk	1300	Banda Sea	1400
Caribbean Sea	1400	Andaman Basin	2000
North Caribbean	2000	Gulf of Mexico	2000
Beaufort Sea	3000	South China Sea	3000
Barent Sea	3000	Celebes Sea	3000
Aleutian Basin	3000	Fiji Basin	3500
North American Basin	3500	West European Basin	3500
Southeast Indian Basin	3500	Coral Sea	3500
East Indian Ocean	3500	Central Indian Ocean	3500
Southwest Atlantic	3500	East South Atlantic	3500
Southeast Pacific	3500	Guatemala Basin	3500
East Caroline Basin	4000	Marianas Basin	4000
Phillipine Sea	4000	Arabian Sea	4000
Chile Basin	4000	Somali Basin	4000
Mascarine Basin	4500	Guinea Basin	4500
Croset Basin	4500	Brazil Basin	4500
Argentine Basin	4500	Tasman Sea	4500

*Basins marked with a dash can interact with each other except certain areas such as the Isthmus of Panama
